

36-Year Analysis of Commuting Patterns in Ireland (1986–2022)

Claire Mac Donagh

Project Overview

Over the past three decades, transport infrastructure, urban development and sustainability priorities have evolved significantly in Ireland.

This project analyses Irish Census commuting data (1986–2022) to understand:

- How commuting behaviour has changed over time
- Whether private car dependency has increased
- How commuting patterns differ by gender
- How travel behaviour varies across work and education

The goal was to move beyond simple population growth trends and identify structural behavioural changes in transport use.

Data source

Dataset: F7122 - Persons Usually Resident and Present in the State

Source: Central Statistics Office (CSO), Ireland, <https://data.cso.ie>

Time span: 1986 - 2022

Classified by:

1. Census Year
2. Sex
3. Means of Travel
4. At Work, Childcare, School or College

Tools Used

- R
- dplyr
- ggplot2
- tidyverse
- scales
- purrr

Analytical approach

To ensure meaningful comparisons across decades, the analysis focused primarily on proportional measures, not absolute counts. Population growth alone would inflate raw numbers across all travel modes. Therefore, modal share (%) was used to identify real behavioural shifts.

Data preparation included:

- Cleaning variable names
- Converting variables to appropriate types
- Removing non-informative categories
- Reordering travel modes for interpretability
- Creating grouped categories

Key Findings

1. Structural Shift Toward Private Motor Transport

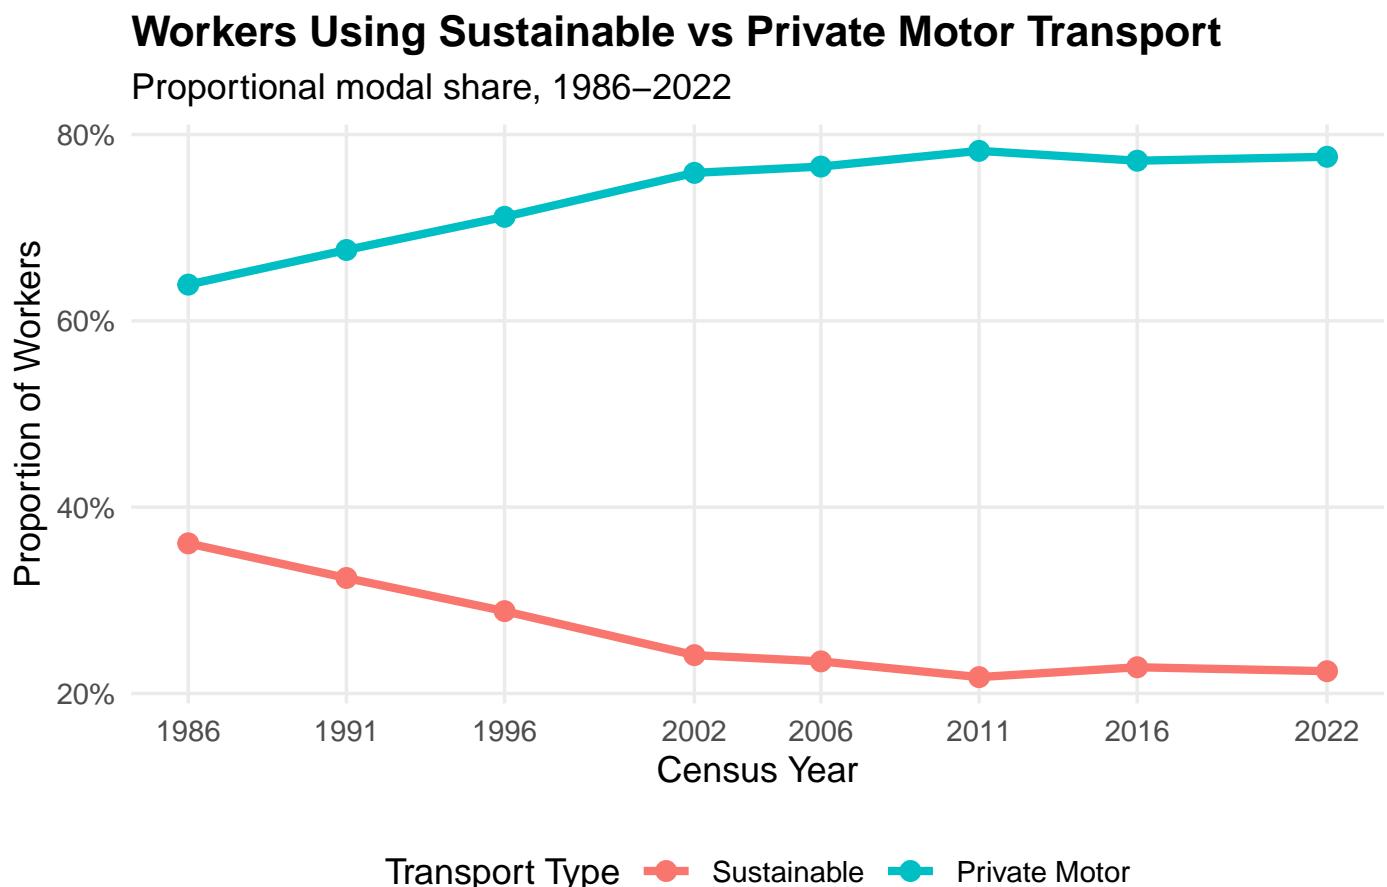

Figure 1: Workers Shift from Sustainable to Private Motor Transport (1986–2022).

KPI: Worker Modal Share (Private vs Sustainable)

Between 1986 and 2011:

- Private motor transport increased from ~64% to nearly 80%
- Sustainable transport declined from ~36% to just over 20%

After 2011, the trend stabilised but did not reverse.

Insight:

Ireland has experienced a long-term structural shift toward car dependency, particularly for work-related commuting.

This has significant implications for:

- Climate policy
- Urban planning
- Public transport investment
- Sustainable mobility strategies

2. Growth in Car Driving as Primary Mode

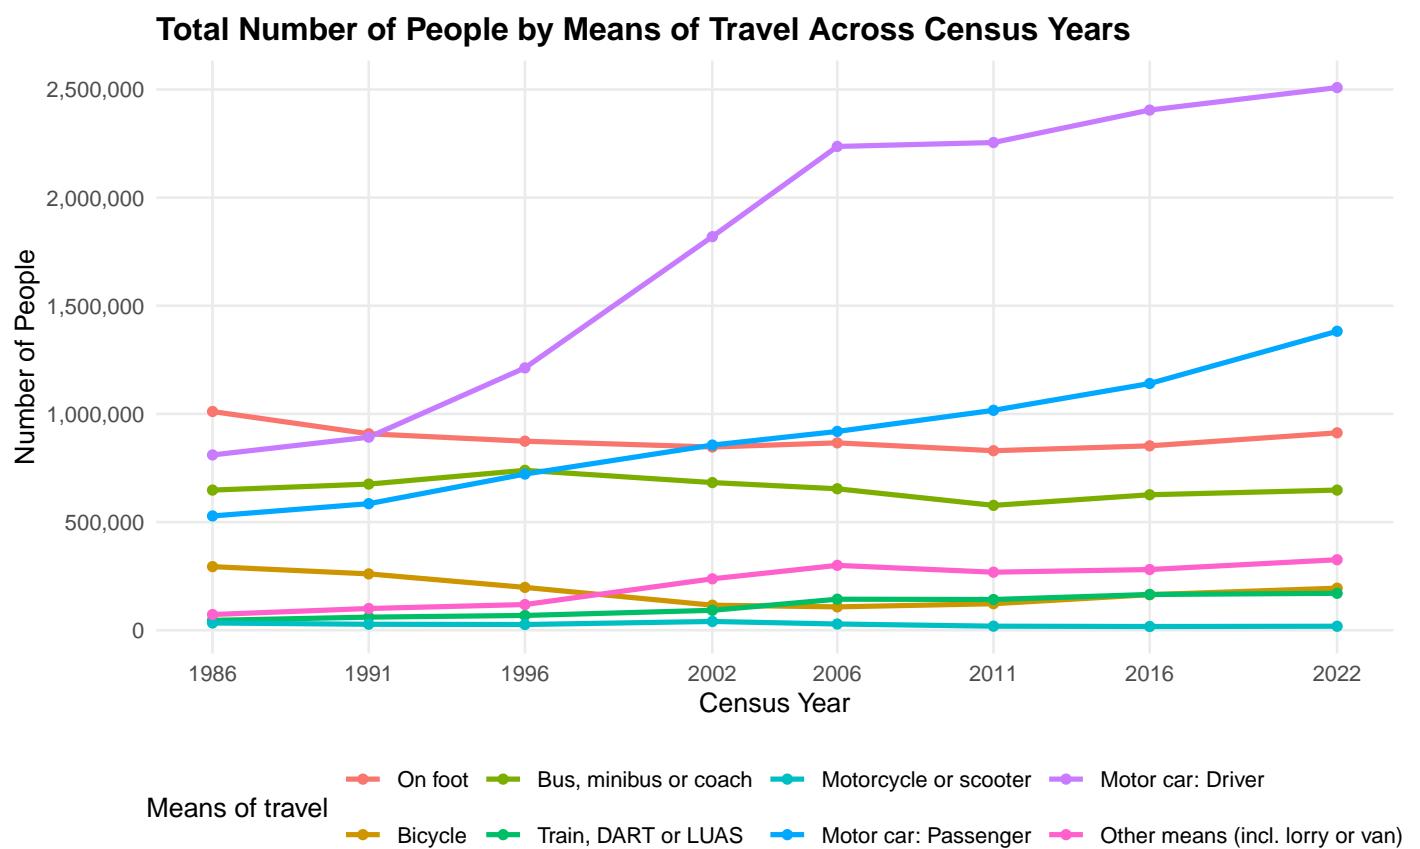

Figure 2: Total Number of People by Means of Travel Across Census Years (1986–2022).

Although total travel increased across all categories, growth was overwhelmingly driven by: *Motor car: Driver*. This indicates that increased travel volume is not merely demographic - it reflects a behavioural shift toward independent car use.

3. Gender Differences in Commuting

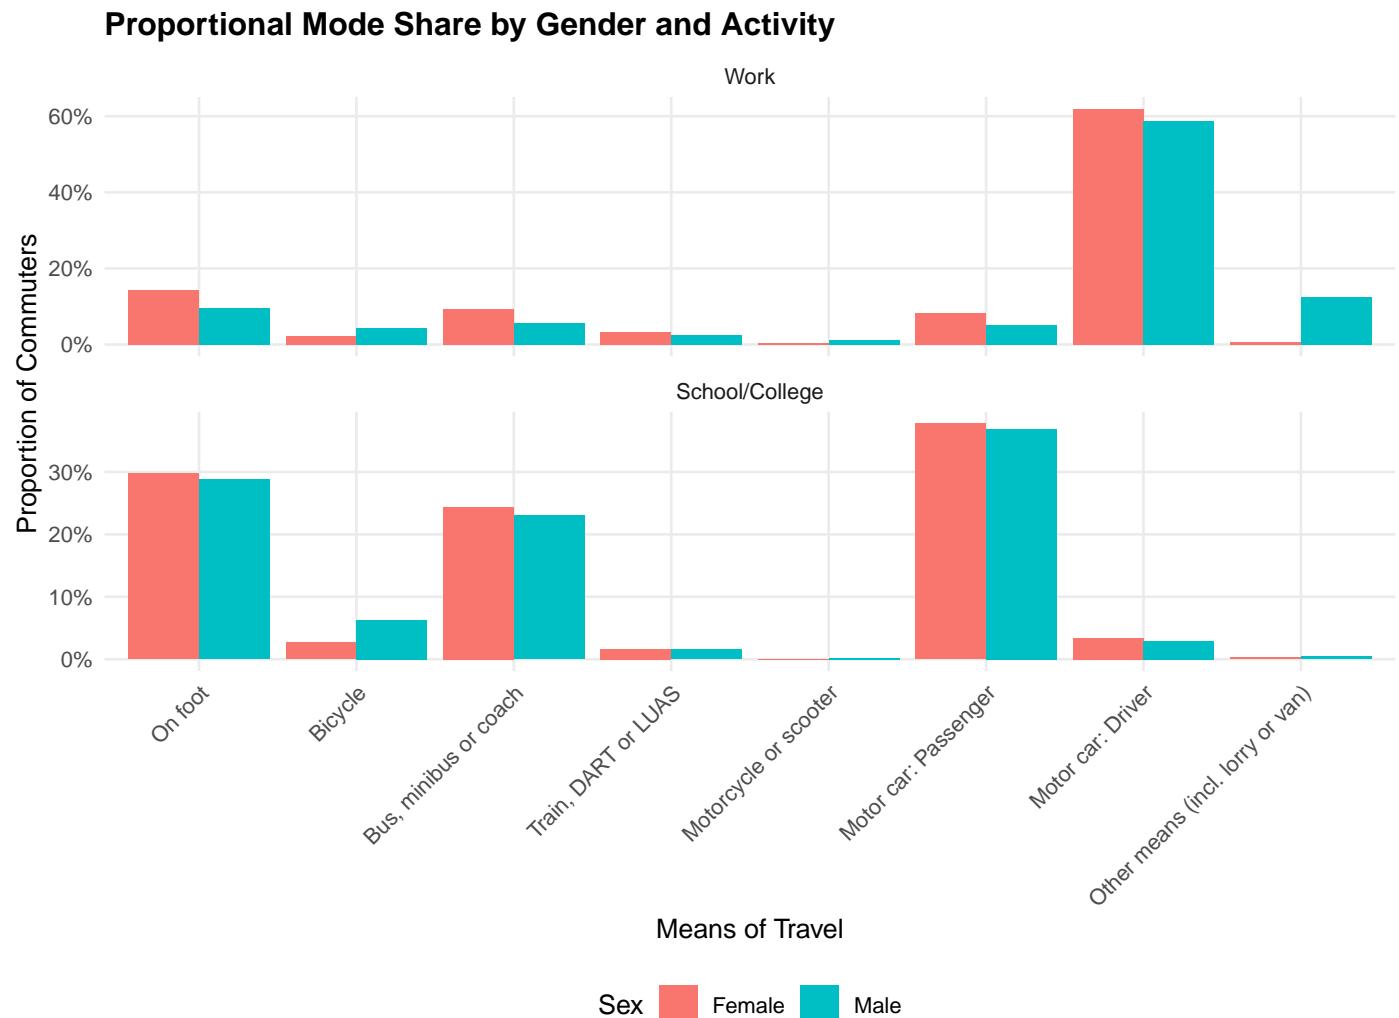

Figure 3: Proportional Mode by Gender Across Work and School/College Activities (1986–2022).

Gender differences exist but are relatively modest overall.

Key patterns:

- Males are more likely to drive
- Females are slightly more likely to walk or use public transport
- Cycling and motorcycling remain strongly male-dominated modes

However, differences across activity type (work vs school) are more pronounced than gender differences.

4. Education Cohort Travel Patterns (Lifecycle Effect)

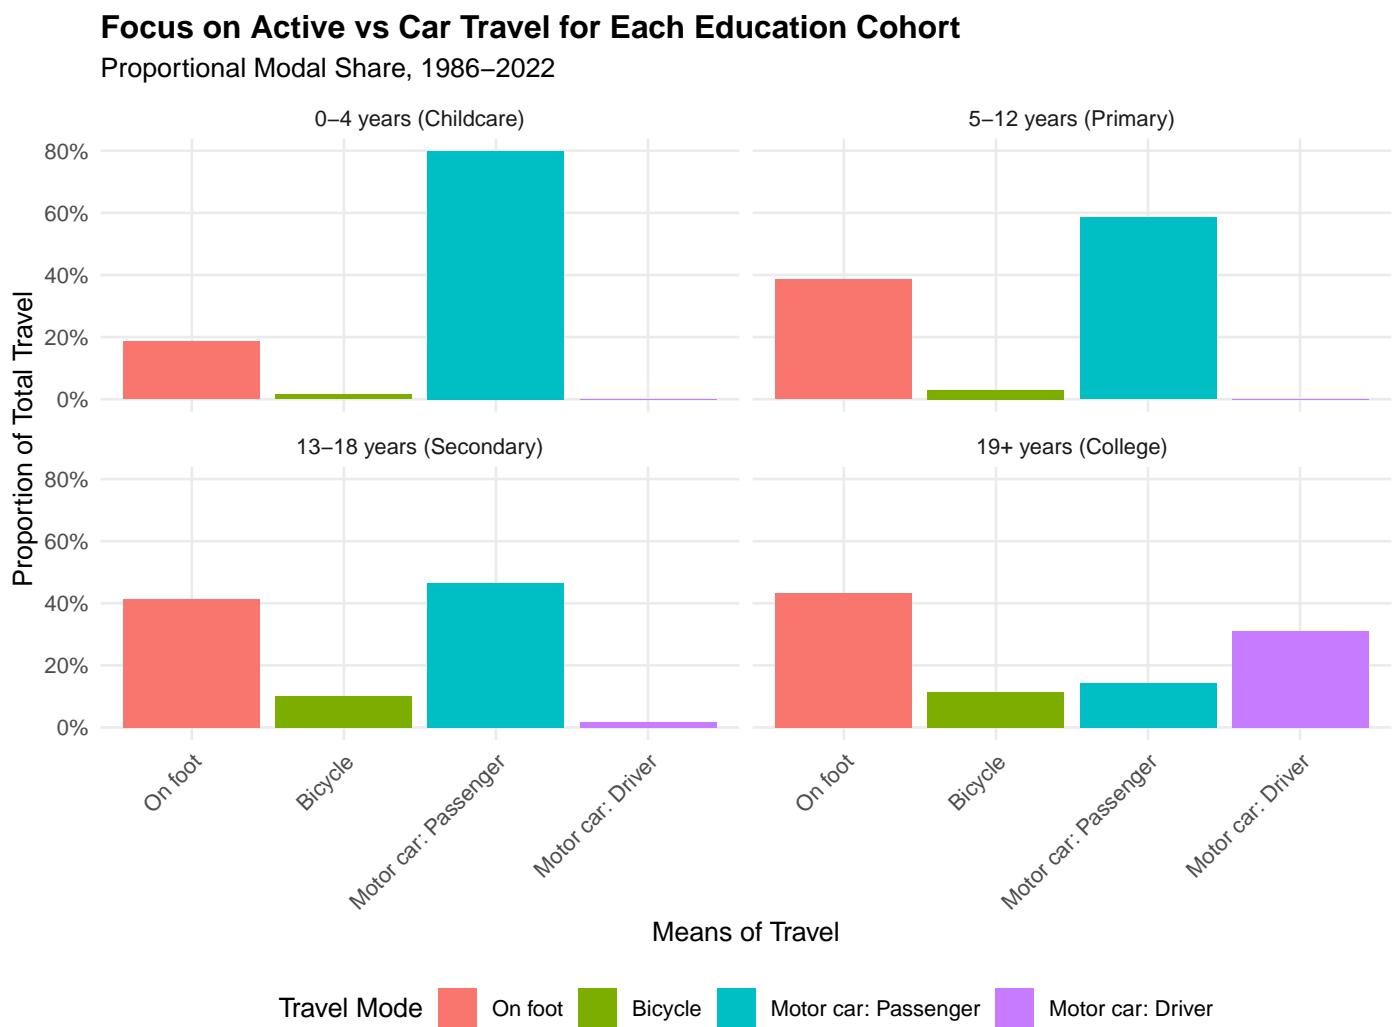

Figure 4: Active Travel Modal Share Across Specific Education Cohorts (Aggregated 1986–2022).

Travel behaviour varies significantly by age group:

| Age Group | Dominant Mode | Key patterns |
|-------------|-------------------------|-----------------------------------|
| 0-4 years | Car Passenger | Heavy reliance on escorted travel |
| 5-12 years | Car Passenger + Walking | Increase in active travel |
| 13-18 years | Walking | Peak independent active travel |
| 19+ years | Car Driver | Transition to independent driving |

Insight:

Car dependency begins early and strengthens as individuals gain independence and travel longer distances.

This suggests long-term behavioural reinforcement of private motor transport.

What This Project Demonstrates

This analysis showcases the ability to:

- Clean and structure real government datasets
- Perform longitudinal analysis
- Use proportional metrics correctly
- Avoid misleading absolute trends
- Segment data by demographic group
- Communicate insights clearly
- Translate data into policy-relevant conclusions

Business & Policy Implications

The sustained dominance of private motor transport suggests:

- Infrastructure investment in sustainable transport may not yet be sufficient to reverse long-term trends
- Behavioural change requires structural incentives, not short-term interventions
- Urban design and land-use planning play a major role in commuting behaviour

This analysis highlights the complexity of achieving modal shift toward sustainable mobility.
